Semaphorins are an essential family of guidance cues ubiquitously expressed in various organs, which play diverse developmental, homeostatic, and pathological roles. Semaphorin 3E (Sema3E), initially identified as a neuronal chemorepellent, is involved in the regulation of cell migration, proliferation, and angiogenesis. However, expression and function of Sema3E in allergic asthma has not been extensively investigated. We determined the expression of Sema3E in the airways and its effect on airway inflammation, hyperresponsiveness, and remodeling as pathological features of allergic asthma provoked by house dust mite in vivo. Our data indicate that exposure to house dust mite markedly reduces Sema3E expression in mouse airways. More important, replenishment of Sema3E by intranasal administration of exogenous Sema3E protects mice from allergic asthma by reducing eosinophilic inflammation, serum IgE level, and T helper cell 2/T helper cell 17 cytokine response. The regulatory effect of Sema3E on cytokine response was sustained on allergen recall response in the lymph nodes and spleen. Furthermore, goblet cell hyperplasia, collagen deposition, and airway hyperresponsiveness were significantly diminished on Sema3E treatment. The inhibitory effect of Sema3E was associated with a reduction of pulmonary CD11b+ conventional dendritic cells and regulation of CD4+ T-cell cytokine response. Collectively, our data represent a novel approach to treating allergic asthma via regulation of immune response to house dust mite. (Am J Pathol 2017, 187: 1566–1576; http://dx.doi.org/10.1016/j.ajpath.2017.03.008)

Asthma is a multifaceted disease of the airways associated with chronic inflammation, bronchoconstriction, remodeling, and airway hyperresponsiveness (AHR).1 The prevalence of allergic asthma has been remarkably increasing for the past decades.2 Therefore, development of new strategies to treat allergic asthma, in particular severe refractory form of the disease, is an urgent unmet clinical need. However, novel therapeutic approaches fail to significantly alleviate the cardinal features of asthma, especially AHR and remodeling.3–5

Continuous exposure with innocuous aeroallergens, such as house dust mite (HDM), deviates the immune system toward a granulocytic rich response. It perpetuates the airway inflammation that leads to a massive structural alteration of the airways and subsequently AHR as the hallmark of disease pathology.6 However, the mechanisms underlying airway remodeling and AHR could spontaneously develop independent of inflammatory response.7,8 Also, a considerable portion of asthmatic patients have a T helper cell (Th) 2-low noneosinophilic phenotype that poorly responds to current anti-inflammatory treatments (eg, corticosteroids).3,9,10 Thus, efficient therapeutic strategies for allergic asthma should be able to target various arms of the disease, including both inflammatory and structural compartments of the airways.

Semaphorins are guidance cues that play diverse roles, such as immune regulation, angiogenesis, cell...
proliferation, and migration. Various semaphorins have been reported to exert proinflammatory or anti-inflammatory responses in a context-dependent manner. For instance, Semaphorin 3E (Sema3E) is able to dualistically promote or suppress inflammation in the obesity model or atherosclerotic plaques, respectively, via regulation of macrophage functions. Sema3E is ubiquitously expressed in different cell types, including adipocytes, macrophages, tumor cells, hepatocytes, osteoblasts, and dendritic cells. It is involved in essential cellular functions that are dysregulated in allergic asthma. We have previously reported that in vitro treatment of human airway smooth muscle (ASM) cells with Sema3E inhibits growth factor–induced proliferation and migration considered as fundamental mechanisms contributing to airway remodeling. This effect was associated with suppression of mitogen-activated protein kinase, phosphatidylinositol 3-kinase, and Ras-related C3 botulinum toxin substrate 1 GTPase signaling. Furthermore, we have recently revealed that genetic abrogation of Sema3E in mice leads to a hypergranulocytic phenotype, which is associated with enhanced AHR, remodeling, and Th2/Th17 inflammation. Sema3E was also shown to reduce neutrophil recruitment to the airways on HDM reexposure. How- ever, the therapeutic potential of Sema3E in allergic asthma has remained to be understood.

Our goal was first to determine the expression of Sema3E in the airways and then to address the in vivo effect of Sema3E on allergic airway inflammation, remodeling, and AHR using the HDM model of the disease. We also aimed to understand the mechanisms underlying Sema3E effects on the allergic asthma model. We found that Sema3E expression was down-regulated in murine airways on HDM sensitization and challenge. Administration of exogenous recombinant Sema3E protected mice from HDM-induced airway inflammation, mucus overproduction, collagen deposition, and AHR. The mechanism underlying the Sema3E effect on the HDM mouse model of allergic asthma was mediated, at least in part, via regulating cytokine response, pulmonary dendritic cell (DC) recruitment, and function. Taken together, our findings reveal a major regulatory role of Sema3E in allergic asthma.

Materials and Methods

Animals

Female 6- to 8-week-old BALB/c mice were purchased from the Central Animal Care Services at the University of Manitoba (Winnipeg, MB, Canada). All of the mice were maintained at the Central Animal Care Services facility under specific pathogen-free conditions and used according to the guidelines stipulated by the Canadian Council for Animal Care.

House Dust Mite Exposure Model

Lyophilized HDM protein extract was obtained from Greer Laboratories (Lenoir, NC), which was reconstituted in sterile saline as 2.5 mg/mL stock concentration before treatment. A working concentration (25 μg per mouse in 35 μL of saline) was freshly prepared, and an acute model of the disease was established via intranasal administration under gaseous anesthesia for 5 days per week during 2 consecutive weeks. Recombinant mouse Sema3E-Fc (10 μg/kg in sterile phosphate-buffered saline) was administered through the intranasal route 1 hour before each HDM exposure. The control group received sterile saline-Fc at the same time points. All experiments were performed 48 hours after the last HDM exposure, unless otherwise indicated. Murine Sema3E-Fc recombinant protein was produced as fusion protein N-terminal to a functional mouse γc Fc domain. Complete cDNA was amplified from total RNA of a mouse brain, ligated into pFUSE-mfc1 vector, and electroporated into CHO cells. Finally, secreted Sema3E-Fc protein was purified from the conditioned media by protein A-affinity chromatography, as described previously.

Immunofluorescence

Formalin-fixed lung tissues were paraffin embedded, and sections (5 μm thick) were prepared, dewaxed in xylene, and rehydrated through graded concentrations of alcohol to water, and then boiled for 10 minutes in sodium citrate buffer. Then, sections were incubated with blocking buffer for 1 hour at room temperature. Rabbit anti-Sema3E antibody (2.5 μg/mL; Abcam, Cambridge, MA) or isotype control IgG (Jackson ImmunoResearch Laboratories, West Grove, PA) was added, and sections were incubated overnight at 4°C. Slides were then washed twice with tris-buffered saline, followed by incubation with Alexa-488–conjugated anti-rabbit secondary antibody for 1 hour at room temperature away from light. After an extensive wash with tris-buffered saline, slides were finally mounted with a DAPI-containing antifade reagent (Life Technologies Inc., Burlington, ON, Canada) and visualized by Axioskop 2 mot plus microscope using AxioVision software version 4.8 (Carl Zeiss, Inc., Thornwood, NY). Integrated density of Sema3E immunostaining in the airways was compared between saline and HDM-challenged mice by ImageJ version 1.51j8 (NIH, Bethesda, MD; http://imagej.nih.gov/ij).

Airway Responsiveness

Mice were anesthetized and cannulated via the trachea 48 hours after the last HDM challenge. An increasing gradient of methacholine dose was administered intratracheally, and AHR parameters, including airway resistance, tissue resistance, and tissue elastance, were measured by using a FlexiVent small animal ventilator system (SCIREQ, Montreal, QC, Canada).
Preparation and Processing of BAL Fluid

Bronchoalveolar lavage (BAL) was performed with two instillations of 1 mL of sterile saline containing 0.1 mmol/L EDTA. Red blood cells were lysed using ammonium-chloride-potassium buffer. Total cells in BAL fluid (BALF) were spun down at 300 × g for 5 minutes, and supernatants were stored at −80°C to measure cytokines. Cytospins from BALF cells were prepared and stained, and different inflammatory cell types were characterized morphologically and counted by two individuals in a blind manner (H.M. and L.S.).

Lung Histology

Dissected left lobes of mouse lungs were inflated, fixed, and embedded in paraffin. Then, sections were stained with hematoxylin and eosin, periodic acid–Schiff, and Sirius red for assessing the presence of airway inflammation, mucus overproduction, and collagen deposition, respectively. Slides were quantified by pathological scoring from 0 (the lowest staining intensity) to 5 (the highest staining intensity) in a blind manner (H.M. and L.S.).

Quantification of Cytokines and Immunoglobulins

An enzyme-linked immunosorbent assay was performed to measure IL-4, IL-5, IL-9, IL-12, IL-17A, and interferon (IFN)-γ in BALF supernatants, according to the manufacturer’s instructions. Plates were read with SpectraMax plate reader and analyzed with SoftMax Pro software version 5.4.1 (Molecular Devices, Sunnyvale, CA). All cytokine enzyme-linked immunosorbent assay kits were from BioLegend (San Diego, CA). A similar procedure was performed on supernatants obtained from the culture of mediastinal lymph node (MLN) cells, splenocytes, or coculture of lung DC subsets and splenic T cells 72 hours after HDM or vehicle stimulation.

Figure 1 Sema3E expression is reduced in the airways of HDM-exposed mice. A: Allergic airway disease model was established by intranasal (IN) administration of HDM for 2 weeks. B and C: Mouse Sema3E expression was investigated by performing immunofluorescence staining on airway sections obtained from mice exposed to either saline (B) or HDM (C). D: Staining with isotype control (IC) antibody does not show cross-reactivity. Sema3E expression was visualized with ×100 and ×200 magnifications after incubation of tissue sections with anti–Sema3E-specific primary antibody, fluorescein isothiocyanate–labeled secondary antibody, and counterstaining of nuclei with DAPI. E: Intensity of Sema3E staining was quantified by measuring fluorescence-integrated density. Data are expressed as means ± SEM. n = 4 mice per group (B–E). *P < 0.05 versus saline. Scale bars: 20 μm (B–D, top row); 50 μm (B–D, bottom row). Original magnifications: ×100 (B–D, top row); ×200 (B–D, bottom row).
Serum was obtained from the mice exposed intranasally with saline-Fc or HDM-Fc with or without Sema3E-Fc. Total and HDM-specific IgE and IgG1 levels were quantified using commercial kits, according to the manufacturer’s instructions (Southern Biotech, Birmingham, AL), as we described previously.32

Flow Cytometric Analysis of Intracellular Cytokines

Briefly, MLN or spleen was collected and a single-cell suspension was prepared by using a cell strainer. The cells were resuspended at a concentration of $4 \times 10^6$ cells/mL in Dulbecco’s modified Eagle’s medium supplemented with 10% fetal bovine serum, 2 mmol/L L-glutamine, 100 U/mL penicillin, 100 $\mu$g/mL streptomycin, and $5 \times 10^{-5}$ mmol 2-mercaptoethanol, plated in 24-well tissue culture plates. Then, MLN or spleen cells were incubated with a freshly prepared cocktail containing 50 ng/mL phorbol myristate acetate, 500 ng/mL ionomycin, and $10 \mu$g/mL brefeldin A, all from Sigma-Aldrich (Oakville, ON, Canada) for 4 hours at 37°C and 5% CO2. Extracellular staining was performed by using anti-mouse CD3 eFluor 450 (clone 17A2; eBioscience), anti-mouse CD11c-allophycocyanin (clone 418; eBioscience), MHCII eFluor 450 (clone M5/114.15.2; eBioscience), CD11b- phosphatidylethanolamine-Cy7 (clone M1/70; BioLegend), and CD103-PerCP-Cy5.5 (clone 2E7; BioLegend) antibodies. Finally, pulmonary CD11b$^+$ or CD103$^+$ DC subsets (pregated as non-fluorescent F4/80$^-$CD11c$^+$MHCIIhi) were sorted using a BD FACSAria-III Digital Cell Sorter (BD Biosciences) and co-cultured with splenic T cells in 1:10 ratios for 72 hours to measure the cytokine response.

Statistical Analysis

GraphPad Prism 5.0 software (Graphpad Software Inc., La Jolla, CA) was used for statistical analysis, and values were presented as the means ± SEM of at least three independent experiments. Depending on the number of groups and treatments, data were analyzed by unpaired $t$-test, one- or two-way analysis of variance, followed by the Bonferroni’s multiple comparisons post hoc test. Differences were considered to be statistically significant at $P < 0.05$. 

Figure 2  Sema3E prevents HDM-induced airway hyperresponsiveness (AHR) and recruitment of inflammatory cells to the airways. A: Exogenous recombinant Sema3E-Fc was administered intranasally (IN) 1 hour before each HDM exposure for 2 weeks. B–F: Sema3E treatment hampers HDM-induced airway resistance (B), tissue resistance (C), and tissue elastance (D). Total inflammatory cells (E) and eosinophils (F) are reduced in BALF on Sema3E treatment compared to those of HDM-challenged mice. Data are expressed as means ± SEM, $n = 3$ to 5 mice per group (B–F). *$P < 0.05$, **$P < 0.01$, and ***$P < 0.001$ versus HDM-Fc.
Results

HDM Exposure Down-Regulates Sema3E Expression in Airways

Because repeated exposure to HDM induces AHR, inflammation, and tissue remodeling, we exposed Balbc mice with this clinically relevant allergen for 2 consecutive weeks (Figure 1A).31,34,35 Then, Sema3E immunoreactivity was assessed in the allergic airways and compared with that of the saline-treated control group. Immunofluorescence staining on lung tissue sections revealed that Sema3E is highly expressed in saline-treated mice, especially in the airway epithelium (Figure 1B). In contrast, HDM sensitization and challenge dramatically decreased Sema3E expression (Figure 1C). Staining with isotype control antibody confirmed the specificity of Sema3E immunoreactivity (Figure 1D). Intensity of Sema3E immunostaining in the airways was significantly reduced on HDM exposure (Figure 1E). Decreased expression of Sema3E on HDM challenge suggests an unknown key role of this protein in airway homeostasis, which is impaired in asthmatic conditions.

Sema3E Treatment Prevents HDM-Induced AHR, Remodeling, and Inflammation

We previously reported an inhibitory effect of Sema3E on ASM cell proliferation and migration in vitro28 and also a protective role of this protein in the HDM model of asthma using Sema3e−/− mice.29,30 These findings combined with decreased expression of Sema3E (Figure 1) encouraged us to examine whether Sema3E has a potential therapeutic effect on allergic asthma in vivo. Therefore, we first treated mice with either Sema3E-Fc or saline-Fc, followed by intranasal HDM or saline exposure 1 hour later for 2 consecutive weeks (Figure 2A). We observed a significant decrease in HDM-induced airway resistance (Figure 2B) as a key measure of lung function in mice that received Sema3E-Fc before HDM exposure compared to those that received saline-Fc alone. Similarly, both tissue resistance (Figure 2C) and tissue elastance (Figure 2D) were decreased on Sema3E treatment. In addition, mice treated with Sema3E-Fc exhibited a reduced number of total inflammatory cells (Figure 2E), particularly eosinophils and, to some extent, neutrophils (Figure 2F) in BALF compared to...
HDM-Fc-treated controls. The inhibitory effect of Sema3E on HDM-induced lung leukocytic infiltration was confirmed by hematoxylin and eosin staining (Figure 3, A and B). Mucus secretion and collagen deposition, two critical facets of airway remodeling in allergic asthma, were significantly decreased by Sema3E administration, as evaluated by periodic acid–Schiff (Figure 3, C and D) and Sirius red staining (Figure 3, E and F) on lung tissue sections, respectively. Together, these data suggest that Sema3E treatment modulates airway inflammation, remodeling, and AHR provoked by HDM.

Sema3E Reduces Cytokine and Antibody Responses during an Allergic Airway Disease

We then investigated the effect of Sema3E-Fc treatment on cytokine response. Compared to the mice given only saline-Fc before HDM challenge, Sema3E-Fc–treated mice showed a significant decrease of IL-4, IL-5, IL-9, and IL-17A. However, IL-12 level in the BALF was not significantly altered on Sema3E-Fc treatment, whereas Sema3E-Fc treatment increased IFN-γ level in the BALF (Figure 4A).

The effect of Sema3E-Fc treatment on Th1/Th2 cytokine response was further investigated by performing flow cytometry on lung-draining MLN ex vivo. Sema3E-Fc decreased HDM-induced intracellular production of IL-4 in CD4⁺ MLN cells (Figure 4, B and C). However, unlike BALF data, Sema3E-Fc did not change intracellular IFN-γ production in CD4⁺ MLN cells (Figure 4, D and E). In vivo administration of Sema3E-Fc decreased IL-4 (Supplemental Figure S1, A and B) and increased IFN-γ (Supplemental Figure S1, C and D) intracellular production in CD4⁺ spleen cells. Collectively, our data suggest that Sema3E’s role in allergic asthma is mediated, at least partially, by the orchestration of inflammatory cytokine response.
The regulatory role of Sema3E in cytokine response encouraged us to examine whether this effect is sustained on HDM recall. MLN single-cell suspensions were isolated from Sema3E-Fc treated and untreated HDM-challenged mice. Then, cells were restimulated with HDM or vehicle in vitro for 72 hours to assess the cytokine response in the supernatant. MLN cells isolated from Sema3E-Fc treated and HDM-exposed mice had a significant decrease in IL-4 level (Figure 5A) after in vitro HDM recall stimulation compared to that of nontreated mice. But, Sema3E did not significantly alter IFN-γ (Figure 5B), IL-17A (Figure 5C), and IL-9 (Figure 5D) levels on HDM restimulation in MLN cells.

To address whether the sustained effect of Sema3E treatment has a potential systemic impact, we studied the cytokine response in splenocytes after HDM recall. Un-stimulated splenocytes from Sema3E-Fc—treated HDM-exposed mice had a significantly lower basal level of IL-4 secretion compared to the HDM-exposed group (Supplemental Figure S2A). Furthermore, in vitro stimulation with HDM increased IFN-γ level in splenocytes obtained from Sema3E-treated HDM-challenged mice (Supplemental Figure S2B). Contrary to the MLN recall data, Sema3E-Fc reduced IL-17A level in response to HDM restimulation in vitro (Supplemental Figure S2C), whereas the IL-9 level did not significantly change (Supplemental Figure S2D). These results suggest that the Sema3E effect on balancing Th1/Th2 cytokine response is sustained during recall response provoked by HDM.

Next, we measured the level of antibodies involved in regulation of allergic response in the serum obtained from Sema3E with or without HDM-treated mice. We observed a significant reduction in total (Figure 6A) and HDM-specific (Figure 6B) IgE synthesis on Sema3E-Fc treatment compared to those of Fc-control group. Similarly, both total (Figure 6C) and HDM-specific (Figure 6D) IgG1 levels, elevated by HDM challenge, were diminished after Sema3E treatment. Therefore, the Sema3E suppressive role in allergic airway inflammation could be mediated in part through down-regulation of HDM-induced IgE and IgG1 synthesis in the serum.

Sema3E Plays a Crucial Role in Regulation of Pulmonary DC Migration and Function in Allergic Airway Disease

Pulmonary DC subsets have an essential role in initiation and maintenance of allergic response. To address whether Sema3E implicates in the regulation of pulmonary DC recruitment, we sensitized mice with a single high dose of HDM for 72 hours with or without prior Sema3E treatment. Total (CD11c+ MHCIIhi) pulmonary conventional DC (cDC) and also CD103+ subset did not significantly change after Sema3E treatment (Figure 7A). In contrast, HDM-induced CD11b+ pulmonary cDC recruitment was markedly reduced on Sema3E treatment (Figure 7, A and B).

Because CD11b+ and CD103+ cDCs have been demonstrated to be essential for shaping the immune response to allergens, we purified these cells from HDM with or without Sema3E-Fc treated mice and then investigated their effect on cytokine response on co-culture...
with T cells in the presence of HDM in vitro. CD11b⁺ pulmonary cDCs from Sema3E-treated mice induced a significant reduction of IL-5 and IL-17A levels (Figure 7C). On the other hand, despite no effect of Sema3E on the pulmonary recruitment of CD103⁺ cDCs, it resulted in decreased IL-17A and increased IFN-γ levels on HDM stimulation in vitro (Figure 7D). Furthermore, we demonstrated that Sema3E high-affinity receptor is constitutively expressed on the surface of both CD11b⁺ and CD103⁺ pulmonary cDCs (Figure 7E), suggestive of a functional role on Sema3E binding. Collectively, these data suggest that the effect of Sema3E in allergic asthma could be mediated by regulation of pulmonary cDC functions.

**Discussion**

Semaphorins are ubiquitously expressed and play diverse roles in many biological processes, including immune regulation; but our understanding of Sema3E expression and function in allergic asthma has been surprisingly limited. In the present study, we demonstrated that Sema3E expression is reduced in the mouse airways on HDM sensitization and challenge. We further revealed that intranasal administration of recombinant Sema3E protects mice from HDM-induced airway inflammation, remodeling, and AHR. This observation suggests that Sema3E could be considered a promising therapeutic option for allergic airway disease that regulates both inflammatory and structural cell functions.

Sema3E immunoreactivity was clearly observed in the airway epithelium of saline-treated mice, which was considerably reduced on HDM challenge. Down-regulation of Sema3E in allergic asthmatic conditions suggests a crucial role of this mediator in airway homeostasis and allergic inflammation. Similar to Sema3E down-regulation, we previously showed a reduced expression of its high-affinity receptor, PlexinD1, on human ASM cells from allergic asthmatic subjects, suggesting a dysregulated expression of both ligand and receptor in allergic asthma. Moreover, PlexinD1 was shown to be expressed on DC and ASM cells in vitro as well as smooth muscle bundle in bronchial biopsy specimens of allergic asthmatics in vivo. We previously revealed that Sema3E modulates growth factor–induced ASM cell proliferation and migration. Taken together, it is tempting to speculate that Sema3E may modulate airway inflammation by regulating DC function, AHR, and tissue remodeling through inhibiting the migration and proliferation of ASM cells. This speculation is in accordance with decreased airway inflammation, AHR, and remodeling observed in HDM-challenged and Sema3E-treated mice compared to the vehicle-treated counterpart.

AHR is a major clinical facet of allergic asthma. Sema3E treatment in mice prevented HDM-induced airway resistance, tissue resistance, and elastance as the characteristic parameters of AHR. A decreased level of IL-4 on Sema3E administration or after recall stimulation may explain, at least in part, the diminished AHR, because IL-4 signaling through STAT6 is required for the development of sustained AHR in mouse models of allergic asthma. Down-regulation of IL-4, as a key player for Ig class switching, by Sema3E treatment may further explain the reduction of proallergic antibody, IgE.
Collagen deposition, considered as a key feature of pulmonary fibrosis in chronic asthma, was reduced on Sema3E treatment. There is no report on the role of Sema3E in pulmonary fibrosis, although a recent study reveals that Sema3E secreted by damaged hepatocytes regulates liver fibrosis. However, Sema7A signaling plays a crucial role in pulmonary fibrosis and remodeling by regulation of phosphatidylinositol 3-kinase/protein kinase B/AKT signaling. Peng et al. have recently reported that genetic deletion of Sema7A receptor, PlexinC1, leads to increased pulmonary fibrosis. Furthermore, endogenous Sema7A has been shown to inhibit up-regulation of profibrotic genes in human fibroblasts. Therefore, the effect of Sema3E on pulmonary fibrosis should be further investigated in a chronic model of allergic asthma.

It has been previously revealed that aeroallergens recruit DCs to the airways, and elimination of cDCs has been proposed to prevent allergic airway inflammation and AHR. Herein, we demonstrate that the inhibitory role of Sema3E in experimental allergic asthma could be mediated via modulating recruitment of CD11b+ cDCs, as Th2 skewing cells, to the airways. Unlike the CD11b+ cDC subset, HDM-induced recruitment of CD103+ pulmonary cDCs was not altered by Sema3E. However, our in vitro evidence indicated Sema3E-mediated regulation of cytokine response by both cDC subsets on co-culture with T cells. Sema3E receptor, PlexinD1, has been previously demonstrated to be highly expressed on bone marrow–derived dendritic cells, as we also showed its surface expression on both pulmonary cDC subsets, which suggests them as responder cells to Sema3E treatment. Decreased recruitment of CD11b+ cDCs into the airways of Sema3E-treated allergic mice indicates that Sema3E acts as a guidance cue for these cells, which is analogous to the original function of semaphorins in axon guidance.

In summary, we report that Sema3E plays an essential immunoregulatory role in experimental allergic asthma. Given that Sema3E expression was reduced in allergic asthma and its administration ameliorated the pathological features of the experimental disease, reintroducing Sema3E to the airways might prove efficacious in the treatment of clinical asthma. This previously unknown role for Sema3E in allergic asthma may lead to developing therapeutic strategies in other diseases involving AHR and airway inflammation.
Acknowledgments

We thank Dr. Sam Kung and Dr. Thomas Murooka for critical reading of the manuscript, Dr. Christine Zhang (Flow Cytometry Core Facility, University of Manitoba) for her help on sorting lung dendritic cell subsets, Sujata Basu (Murine Lung Function Laboratory, Manitoba Institute of Child Health, Winnipeg, MB, Canada) for her assistance on airway hyperresponsiveness measurements, and Anik Muhuri for his assistance on enzyme-linked immunosorbent assay experiments.

H.M. designed and performed the experiments, analyzed results, and prepared the manuscript; L.S. conducted experiments; J.S.D.-C. cloned, expressed, and purified mouse Semaphorin 3E–Fc and revised the manuscript; A.J.H. performed mouse lung mechanics studies; J.E.U. and A.S.G. designed experiments, analyzed data, and prepared the manuscript. All authors revised and approved the final version of the manuscript.
