The intracellular proinflammatory mediator IL-32 is associated with tumor progression; however, the mechanisms remain unknown. We studied IL-32 mRNA expression as well as expression of other proinflammatory cytokines and mediators, including IL-1α, IL-1β, IL-6, IL-8, tumor necrosis factor (TNF)-α, the proangiogenic and antiapoptotic enzyme cyclooxygenase-2, the IL-8 receptor C-X-C chemokine receptor (CXCR) 1, and the intracellular kinase focal adhesion kinase-1. The interaction of IL-32 with expression of IL-6, TNF-α, IL-8, and cyclooxygenase-2 was also investigated. Biopsy specimens of 11 HIV-related, 7 non–HIV-related Kaposi sarcoma (KS) and 7 normal skin tissues (NSTs) of Dutch origin were analyzed. RNA was isolated from the paraffin material, and gene expression levels of IL-32 α, β, and γ isoforms, IL1α, IL1b, IL6, IL8, TNFA, PTGS2, CXCR1, and PTK2 were determined using realtime quantitative PCR. Significantly higher expression of IL-32β and IL-32γ isoforms was observed in HIV-related KS biopsy specimens compared with non–HIV-related KS and NST. The splicing ratio of the IL-32 isoforms showed IL-32γ as the highest expressed isoform, followed by IL-32β, in HIV-related KS cases compared with non–HIV-related KS and NST. Our data suggest a possible survival mechanism by the splicing of IL-32γ to IL-32β and also IL-6, IL-8, and CXCR1 signaling pathways to reverse the proapoptotic effect of the IL-32γ isoform, leading to tumor cell survival and thus favoring tumor progression. (Am J Pathol 2018, 188: 196–203; https://doi.org/10.1016/j.ajpath.2017.08.033)

IL-32 is a proinflammatory and proapoptotic cytokine that plays a role in carcinogenesis,1–6 inflammation,4 and host defense to infectious agents, such as HIV and Mycobacterium tuberculosis.5,6 IL-32 mRNA is preferentially expressed in immune cells.7 IL-32 induces production of proinflammatory cytokines, including tumor necrosis factor (TNF)-α, IL-1β, IL-6, and IL-8 via NF-κB, p38 mitogen-activated protein kinase, and activating protein-1 activation.7 The sources of IL-32 include natural killer cells, T cells, monocytes, endothelial cells, and epithelial cells,8,9 with endothelial cells reported to exhibit the highest expression. Human IL-32 exists as six splice variants (α, β, γ, δ, ε, and ζ).7 The most frequently found isoforms, however, are IL-32 α, β, and γ.7 The IL-32 isoforms probably originate by splicing of pre-mRNA of the isoform IL-32γ.10 IL-32γ is regarded as the most active isoform of the cytokine, whereas splicing of IL-32γ into IL-32β is thought to be a safety switch in controlling the effects of IL-32γ and thereby reducing chronic inflammation.11

IL-32 is being extensively studied and has been implicated in several diseases, ranging from autoimmune disorders (eg, rheumatoid arthritis),12 to chronic obstructive pulmonary disease,13 and to infectious diseases (eg, HIV).6 More recently, it

Supported by the Department of Internal Medicine, Radboud University Medical Center (Nijmegen, the Netherlands; A.J.A.M.v.d.V. and L.A.B.J.). The HIV Research Trust supported part of travel costs to the Netherlands to work on the project (G.S.).

IL-32 in HIV-Related KS

The virus causes formation of KS spindle cells of the endothelial cell lineage; their derivation is still uncertain (ie, whether they are blood vessel or lymphatic vessel endothelial cells). In KS tumors, almost 80% of the KS spindle cells are infected with KSHV, most of which are infected latently with the virus. During this latency, only a few proteins are expressed, which function primarily in maintenance of the viral genome, cellular proliferation, and activation of NF-κB and p38 mitogen-activated protein kinase signaling cascades. Recent studies have proposed cyclooxygenase-2 (COX-2) and its metabolite prostaglandin E2 as two pivotal proinflammatory/oncogenic molecules to play a role in the expression of major KSHV latency-associated nuclear antigen-1. COX-2, an enzyme involved in prostanooid synthesis, has been heavily associated with KSHV latency infection and, thus, KS tumor progression.

This proangiogenic and apoptotic enzyme is up-regulated by mitogenic and inflammatory stimuli and serves to modulate the immune system in favor of KS progression. Sharma-Walia et al demonstrated the great potential of tumor cell death induction by specific inhibition of COX-2. Interestingly, IL-32 expression has been shown to be induced by COX-2 stimulation in cervical cancer, and it has also been recently reported to be proangiogenic. This interaction is a key factor in the mechanisms of immune evasion and progression of KS. Furthermore, KSHV is documented to express a viral IL-6 protein homologous to human IL-6. Zhang et al demonstrated that IL-32 genetic variant rs28372698 is associated with carcinogenesis. On the other hand, Oh et al demonstrated that IL-32γ inhibits tumor growth by inhibiting expression of NF-κB and STAT3. Similarly, Yun et al demonstrated that IL-32β inhibits tumor growth by increasing cytotoxic lymphocyte numbers and by inactivating the NF-κB and STAT3 pathways through modulation of cytokine levels in tumor tissues. These effects may be influenced by the differential role of IL-32 between cell types and its participation in different intracellular pathways, as described previously.

Several studies have reported IL-32 overexpression in tumor cells compared with normal cells, indicating that IL-32 is associated with carcinogenesis. Several studies have reported IL-32 isoform expression in different HIV-related (HIV+) and non–HIV-related (HIV−) Kaposi sarcoma (KS) cases compared with normal skin tissue (NST). IL-32β (A) and IL-32γ (B) mRNA relative expression in KS tumors. The results are shown as mean relative expression calculated relative to the housekeeping gene. The IL-32β expression in HIV-related KS is significantly elevated compared with NST (U-test, two-tailed P = 0.0026). IL-32γ relative expression is also marginally significantly elevated in HIV-related KS compared with NST (U-test, two-tailed P = 0.027); N = 11 HIV−, KS+ (A and B); N = 5 HIV−, KS− (A and B); N = 6 NST (A and B).

Figure 1 IL-32 is a cytokine with antiproliferative activity which function primarily in maintenance of the viral genome, cellular proliferation, and activation of NF-κB and p38 mitogen-activated protein kinase signaling cascades. Recent studies have proposed cyclooxygenase-2 (COX-2) and its metabolite prostaglandin E2 as two pivotal proinflammatory/oncogenic molecules to play a role in the expression of major KSHV latency-associated nuclear antigen-1. COX-2, an enzyme involved in prostanooid synthesis, has been heavily associated with KSHV latency infection and, thus, KS tumor progression. This proangiogenic and apoptotic enzyme is up-regulated by mitogenic and inflammatory stimuli and serves to modulate the immune system in favor of KS progression. Sharma-Walia et al demonstrated the great potential of tumor cell death induction by specific inhibition of COX-2. Interestingly, IL-32 expression has been shown to be induced by COX-2 stimulation in cervical cancer, and it has also been recently reported to be proangiogenic. This interaction is a key factor in the mechanisms of immune evasion and progression of KS. Furthermore, KSHV is documented to express a viral IL-6 protein homologous to human IL-6. Zhang et al demonstrated that IL-32 genetic variant rs28372698 is associated with carcinogenesis. On the other hand, Oh et al demonstrated that IL-32γ inhibits tumor growth by inhibiting expression of NF-κB and STAT3. Similarly, Yun et al demonstrated that IL-32β inhibits tumor growth by increasing cytotoxic lymphocyte numbers and by inactivating the NF-κB and STAT3 pathways through modulation of cytokine levels in tumor tissues. These effects may be influenced by the differential role of IL-32 between cell types and its participation in different intracellular pathways, as described previously.

We have recently demonstrated that individuals bearing the IL-32 genetic variant rs28372698, which leads to increased IL-32γ gene expression and higher production of proinflammatory cytokines, have a higher risk for developing epithelial cell–derived thyroid carcinoma. Moreover, these individuals require higher dosages of radioactive iodide, the standard therapy after thyroidectomy, to achieve successful tumor remission.

Depending on the function of the isoforms, IL-32 has thus far been demonstrated to play a critical role in both tumor progression and inhibition. It has been demonstrated to be overexpressed in tumors, with the IL-32β and IL-32γ isoforms being the most abundant. However, the mechanism behind the tumor progression has not been studied and explained. The IL-32γ isoform has predominantly a pro-apoptotic action and, thus, induces cell death. Nold et al...
demonstrated the potency of IL-32 to induce HIV-infected cells to undergo apoptosis after IL-32 up-regulation. They also demonstrated that on reduction of endogenous IL-32, HIV viral load tremendously increased in these cells compared with cells expressing IL-32. Nevertheless, contrary to this effect, tumor cells have been shown to progress and not to undergo apoptosis, even on high expression of IL-32. Splicing of the IL-32γ isoform into IL-32β has been described before to occur in THP1 cells, which was demonstrated to be relevant within the pathogenesis and severity of rheumatoid arthritis.11 These studies have revealed that the splicing from IL-32γ into IL-32β may be regarded as a safety switch because IL-32β is a less potent proinflammatory mediator than IL-32γ, leading to decreased production of proinflammatory cytokines, such as IL-1β and IL-6. We hypothesized that this splicing mechanism of IL-32γ to IL-32β is a survival mechanism that inhibits tumor cells from going into apoptosis, even with high expression of IL-32γ. In the present study, the role of the survival mechanism that tumor cells might use to survive high expression levels of IL-32γ, which is predominantly proinflammatory and proapoptotic, was studied. The IL-32 splicing pattern in KS was studied to determine its influence on tumor progression. Furthermore, the effect of IL-6, IL-8, TNF-α, COX-2, C-X-C chemokine receptor (CXCR) 1, and focal adhesion kinase (FAK)-1 on tumor progression and apoptosis induction was investigated. With these experiments, we determined the possible interplay between IL-32 and COX-2 and show their interaction in the initiation of tumor survival pathways in KS. Understanding these interactions may be a step forward toward development of an immune-modulating IL-32β-based therapy for KS and other endothelial cell pathologies driven by chronic infections.

Materials and Methods

Study Samples

Patient tissues of HIV-infected KS cases (N = 11) and non–HIV-infected KS cases (N = 7) from patients of Dutch origin, confirmed by histology and immunohistochemistry, were selected from the database of the Department of Pathology, Radboud University Medical Center (Nijmegen, the Netherlands). These samples were selected on the basis of sample availability in the pathology department archives as well as quality and quantity of RNA obtained. Samples with poor quality and/or low RNA yield were excluded from analysis. Patients’ personal details were decoded to maintain confidentiality by giving a study number to all formalin-fixed, paraffin-embedded tissue biopsy specimens. Ethical approval was obtained for all patient tissues.

qPCR Analysis

Per block, five sections (20 μm thick) were cut from formalin-fixed, paraffin-embedded material under semisterile conditions and transferred to a sterile tube. RNA was isolated by lysis and RNA precipitation protocols. Tissue samples were disrupted and homogenized by an overnight incubation with Proteinase K (Qiagen, Valencia, CA). RNA extraction was performed by using RNA-Bee, according to the manufacturer’s protocol (AMS Biotechnology, Abingdon, UK), including chloroform phase separation and isopropanol precipitation. Isolated RNA was subsequently transcribed into cDNA by using random hexamers (Promega, Leiden, the Netherlands), followed by real-time quantitative PCR (qPCR) using the SYBR Green method (Applied Biosystems, Foster City, CA). The following primers were used for detection: IL-32α, 5'-GCTGAGAGCAGCTTCAAAGA-3' (forward) and 5'-GGGCTCCGTAGGACTTGTCA-3' (reverse); IL-32β, 5'-CACTGAGCCTGGTCATCTCA-3' (forward) and 5'-GGGCTTCAGTCCTCTCATGTCATA-3' (reverse); IL-32γ, 5'-AGGCCGGAATGTGAATGTC-3' (forward) and 5'-CCTAATGTGCTGTGACTC-3' (reverse); TNF-α, 5'-GACGTGAGAATGAGAGGAG-3' (forward) and 5'-TCGCAAAAGAGGATTGAG-3' (reverse); IL-8, 5'-AAGAGAGCTGTCCTGAGGAC-3' (forward) and 5'-TGGCTTCTGGCCTGGTGG-3' (reverse); IL-6, 5'-GATACATCCTCAAGCGCATC-3' (forward) and 5'-GTGCCCTTTGTCTGTTTC-3' (reverse); COX-2, 5'-GGTCTGAGGCTTGCTGTGATG-3' (forward) and 5'-GTCCTTTCAAGGAGAATGTC-3' (reverse); CXCR1, 5'-GCATCTGGCGGATATGTC-3' (forward) and 5'-AGAGGATCTCAGCATTGTC-3' (reverse); and FAK-1, 5'-TCTCGGGAAGGAGAATGTC-3' (forward) and 5'-TCTCGGGCATCATACT-3' (reverse).

Data were corrected for expression of the housekeeping gene β2-microglobulin, for which the primers 5'-ATGAGTATGCTCCCTGGTGTG-3' (forward) and 5'-CTGTCCTGCTGCATC-3' (reverse) were used. Gene expression values were calculated using the comparative threshold cycle (Ct) method. The Ct data for the different genes and the housekeeping gene β2-microglobulin were used to generate Ct values (ΔCt = Ct target gene – Ct housekeeping gene). Thereafter, the relative quantity was calculated by 2ΔCt/1000.

Isolation and Stimulation of HUVECs

Human umbilical vein endothelial cells (HUVECs) were isolated from umbilical cords from healthy donors after obtaining informed consent. Cells were cultured in RPMI 1640 medium (Gibco-Invitrogen, Gaithersburg, MD) supplemented with penicillin/streptomycin, glutamine, pyruvate, heat-inactivated pooled human serum (10%), and heat-inactivated fetal bovine serum (10%). HUVECs were cultured in 0.2% w/v gelatinized (Sigma-Aldrich, St. Louis, MO) tissue flasks/plates (Corning Inc., Corning, NY) at 37°C and 5% CO2. HUVECs were stimulated with 50 μg/mL poly(I:C) (Invivogen, Toulouse, France) or in serum-free RPMI 1640 medium. Twenty-four hours after stimulation, total RNA was isolated by adding Tri-reagent (Sigma-Aldrich) to the cells and processed, as described by Heinhuis.
IL-32 in HIV-Related KS

et al. \(^{25}\) Finally, IL-32 mRNA expression was assessed by qPCR.

**Immunohistochemistry**

IL-32 protein expression was evaluated by immunohistochemical staining of formalin-fixed, paraffin-embedded KS tissue sections. To remove the paraffin, tissues were incubated twice in xylene and successively in 100%, 96%, and 70% alcohol for 5 minutes each step. Antigens were retrieved with citrate buffer for 2 minutes in the microwave (800 W) and 10 minutes at room temperature citrate buffer: pH = 6.0, 16.4 mL sodium citrate (0.1 mol/L) with 3.6 mL citric acid (0.1 mol/L) in 180 mL H\(_2\)O. The endogenous peroxidase activity was blocked with 3% H\(_2\)O\(_2\) in methanol (800 W) and 10 minutes at room temperature citrate buffer: \(0.1 \text{ mol/L} \times 180 \text{ mL} \) sodium citrate (0.1 mol/L) with 3.6 mL citric acid (0.1 mol/L) in 180 mL H\(_2\)O. The endogenous peroxidase activity was blocked with 3% H\(_2\)O\(_2\) in methanol for 10 minutes and subsequently with the avidin/biotin blocking kit, according to the manufacturer’s protocol (Vector Laboratories, Burlingame, CA). Sections were incubated with the first antibody (polyclonal goat anti-human IL-32 AF3040 antibody or goat polyclonal IgG isotype control AB-108-C; R&D Systems, Minneapolis, MN), both 2.5 \(\mu\)g/mL in PBS supplemented with 5% goat serum overnight at room temperature. After washing with PBS, sections were incubated with the second antibody (rabbit anti—goat-BIOT Vector BA-5000; Vector Laboratories), 1:500 diluted in PBS supplemented with 5% rabbit serum, for 30 minutes at room temperature. The ABC–horseradish peroxidase complex (ABCkit-HRP Vector PK-6101; Vector Laboratories), 1:200 diluted in PBS, was applied to the sections for 30 minutes at room temperature. The substrate solution was added for 5 minutes at room temperature. The substrate solution was added for 5 minutes for visualizing the reaction. The sections were counterstained with hematoxylin for 30 seconds at room temperature. The slides were dehydrated with consecutive incubation in 70%, 96%, and 100% alcohol and xylene (two times) for 5 minutes each step. Sections were mounted in Permount (Thermo Fisher Scientific, Waltham, MA).

**Statistical Analysis**

To determine significant differences between the test samples against the controls, \(U\)-tests were used to determine the

two-tailed $P$ values. To account for the comparisons of normal skin tissue (NST) versus HIV$^+$ KS$^+$ and NST versus HIV$^-$ KS$^+$, a two-tailed $P < 0.025$ was considered statistically significant. The analyses were performed using GraphPad Prism version 5 (GraphPad Software, Inc., La Jolla, CA).

Results

General Characteristics of the Data

The general characteristics of the data are listed in Table 1.

IL-32$\beta$ and IL-32$\gamma$ Isoform mRNA Is Abundantly Expressed in KS

To investigate whether IL-32 is expressed in KS, qPCR was used. Expression of IL-32 isoforms was observed in KS cases (Figure 1), with abundant quantities of IL-32$\beta$ and IL-32$\gamma$ isoforms in particular. IL-32$\alpha$ was not detected in KS and NST (data not shown). IL-32$\beta$ showed significantly elevated expression levels in HIV-related KS compared with NST (Figure 1A). HIV-related KS cases also showed marginally statistically significant high levels of IL-32$\gamma$ compared with normal skin controls (Figure 1B).

IL-32 Protein Quantities Are More Abundant in HIV-Related KS

To assess IL-32 protein levels, immunohistochemical staining was performed for IL-32 in HIV-related KS. Cases with the highest and lowest levels of IL-32 mRNA were selected. High IL-32 protein expression was observed in HIV-related KS compared with isotype control. Corresponding high levels of IL-32 protein were detected in high IL-32 mRNA expressing tissues. Also, hematoxylin and eosin staining of HIV-related KS and non–HIV–related KS was performed, and the degree

Figure 3 Relative expression of selected proinflammatory cytokines in HIV- and non–HIV-related Kaposi sarcoma (KS). A–F: IL-8 (A), C-X-C chemokine receptor (CXCR) 1 (B), IL-6 (C), IL-1$\alpha$ (D), IL-1$\beta$ (E), and cyclooxygenase (COX)-2 (F) mRNA relative expression shows higher expression in HIV-related KS compared with normal skin tissue (NST). G: Tumor necrosis factor (TNF)-$\alpha$ shows lower expression in both HIV- and non–HIV-related KS compared with NST. H: Focal adhesion kinase (FAK)-1 shows significantly increased expression in non–HIV-related KS compared with NST ($U$-test, $P < 0.025$). A: $N = 7$ HIV$^+$, KS$^+$; $N = 5$ HIV$^-$, KS$^+$; $N = 5$ NST. B: $N = 8$ HIV$^+$, KS$^+$; $N = 5$ HIV$^-$, KS$^+$; $N = 5$ NST. C: $N = 5$ HIV$^-$, KS$^+$; $N = 7$ NST; $N = 5$ HIV$^+$, KS$^+$; $N = 4$ HIV$^-$, KS$^+$; $N = 6$ NST; $N = 3$ HIV$^+$, KS$^+$; $N = 4$ HIV$^-$, KS$^+$; $N = 3$ NST; $N = 8$ HIV$^+$, KS$^+$; $N = 5$ HIV$^-$, KS$^+$; $N = 5$ NST; $N = 11$ HIV$^+$, KS$^+$; $N = 5$ HIV$^-$, KS$^+$; $N = 4$ NST; $N = 8$ HIV$^+$, KS$^+$; $N = 5$ HIV$^-$, KS$^+$; $N = 4$ NST.
of inflammation in the same cases was assessed. More cellularity and increased numbers of lymphocytes and plasma cells were observed in non-HIV KS (Figure 2).

IL-8, CXCR1, IL-6, IL-1α, IL-1β, and COX-2 Relative Expression Levels Are Moderately Elevated in HIV-Related KS, whereas TNF-α and FAK-1 Are Moderately Down-Regulated

To investigate the role of other selected proinflammatory cytokines and mediators in the tumor progression and to test our hypothesis of COX-2 and IL-8 involvement, the mRNA expression levels of these cytokines were determined by qPCR. FAK-1 (Figure 3H) showed significantly increased expression in non–HIV-related KS compared with NST. IL-8 (Figure 3A), CXCR1 (Figure 3B), IL-6 (Figure 3C), IL-1α (Figure 3D), IL-1β (Figure 3E), and COX-2 (Figure 3F) showed higher expression in HIV-related KS compared with non–HIV-related KS and NST. TNF-α (Figure 3G) showed lower expression in HIV- and non–HIV-related KS compared with NST.

IL-32 Splicing in KS

To investigate the relative expression of IL-32 in KS compared with normal expression in uninfected skin tissue and virus-infected epithelial cells, qPCR was conducted on poly(I:C) stimulated HUVECs. To investigate the relative quantities of the different IL-32 isoforms, the ratio of IL-32γ/IL-32β was calculated. The IL-32γ/IL-32β (Figure 4B) ratio was statistically significantly increased in HUVECs stimulated with poly(I:C) compared with medium control. The splicing ratio in HIV-related KS was significantly reduced compared with NST (Figure 4A).

IL-32 Carcinogenesis Model

We propose IL-32 plays a role in carcinogenesis through the induction of IL-8 production. IL-8 is then excreted to the extracellular environment, where it interacts with its receptor CXCR1 and initiates the IL-8 signaling pathway, which occurs through FAK-1 as its downstream signaling molecule. In turn, this signaling pathway of IL-8 plays a role in tumor survival by production of cell survival proteins. KS seems to be using this mechanism, because increased IL-32γ, IL-32β, IL-8, CXCR1, and FAK-1 expression was observed. Interestingly, KS showed a decreased IL-32γ/IL-32β splicing ratio compared with NST, whereas poly(I:C) stimulated HUVECs showed an increased IL-32γ/IL-32β splicing ratio. This observation is interesting and indicates that human herpes virus-8–induced KS behaves differently from other viral infectious agents, which usually lead to increased IL-32γ/IL-32β splicing ratios. We propose IL-32 plays a role in carcinogenesis through the splicing of the proapoptotic IL-32γ isoform to its lesser potent isoform IL-32β and eventually to the IL-32α isoform. We propose that this splicing mechanism plays an important role in the balance between apoptosis and survival among other mechanisms. The model in Figure 5 shows the interaction between IL-32 and IL-8. Furthermore, the key mechanisms and mediators that play a role in the balance between apoptosis and cell survival with respect to IL-32 involvement are shown.

Discussion

In this study, elevated expression of IL-32γ and IL-32β isoforms was observed in HIV-related KS cases. The current data show that IL-32γ and IL-32β isoforms are significantly
antiviral effect of IL-32 toward HIV-1 and proposed that IL-32 is a natural inhibitor of the virus. The KSHV-8 virus, on the other hand, uses viral IL-6, a viral analog of human IL-6, which is induced by IL-32 to stimulate cells and, thus, bind to gp130, contributing to the pathogenic processes involved.\textsuperscript{15} HIV-related KS tumors were observed to exhibit a significantly higher IL-32$\beta$ to IL-32$\gamma$ splicing activity. This splicing activity was much more efficient than in NST. Furthermore, HIV-related KS showed a trend toward increased expression of IL-1$\alpha$, IL-1$\beta$, IL-8, IL-6, CXCR1, and COX-2. Taken together, these observations suggest KS as an efficient tumor in using the two proposed survival mechanisms. These data further indicate that tumor cells may use splicing activity of IL-32$\gamma$ to IL-32$\beta$ and up-regulation of IL-8 and IL-6 signaling. This leads us to further speculate on the involvement of IL-8 and IL-6 signaling in the survival mechanism of tumor cells, thus favoring tumor progression. TNF-\textalpha and FAK-1 also showed a tendency of decreased expression in HIV-related KS compared with NST and non-HIV-related KS. This tendency is worth exploring further. We can speculate the tendency to be because of the initial levels of IL-32$\gamma$ and IL-32$\beta$. The high splicing activity of IL-32$\gamma$ to IL-32$\beta$ in HIV-related KS may explain the decreased tendency of TNF-\textalpha expression compared with non-HIV-related KS and NST because the IL-32$\beta$ isoform is a less potent proinflammatory cytokine compared with the IL-32$\gamma$ isoform.

The current study has several limitations, mainly the lack of cell culture experiments using KS cell lines to explicitly study the proposed mechanisms separately. Nevertheless, this is the first study, to our knowledge, to explore these pathways in KS tumor progression.

In conclusion, our findings bring into perspective key matters regarding KS tumor cell survival. HIV- and non-HIV-related KS tumors show efficient IL-32$\gamma$ to IL-32$\beta$ splicing activity compared with NST. We speculate that the splicing of IL-32$\gamma$ to IL-32$\beta$ serves as one of the survival mechanisms used by KS cells. Furthermore, the trend toward increased IL-8, IL-6, IL-1$\alpha$, IL-1$\beta$, CXCR1, and COX-2 expression also seems to be following the same trend of being most evident in KS.

We propose further studies into these novel pathways of elevated IL-8 signaling and IL-32 splicing that tumor cells may be using for their survival, because these findings may serve as an important cornerstone for cancer therapy in the future.
